ROUGH CUT OF PROVEN WORK ON \mathcal{H} .

MILES JOHNSON & NATALIE STEWART

1. Introduction

Let S_{2n+r} be the symmetric group on 2n+r indices with $2n+r \geq 2$, let $\mathscr{H} = \mathscr{H}_{k,q}(S_{2n+r})$ be the corresponding Hecke algebra over field k with parameter $q \in k^{\times}$ having square root $q^{1/2}$, and let $\{T_i\}$ be the reflections generating \mathscr{H} . Let $[m]_q = 1 + q + \cdots + q^{m-1}$ be the q-number of m. Let e be the smallest positive integer such that $[e]_q = 0$, and set $e = \infty$ if no such integer exists. Either q = 1 and e is the characteristic of k (with 0 replaced by ∞), or $q \neq 1$ and q is a primitive eth root of unity.

Throughout the text, we will refer to partitions of 2n+r; identify each partition with a tuple $\lambda=(\lambda_1^{a_1},\ldots,\lambda_l^{a_l})$ having $\lambda_i>\lambda_{i+1},\ a_i>0$, and $\sum_i a_i\lambda_i=2n+r$. Identify each of these with a subset $[\lambda]\subset\mathbb{N}^2$ as defined in Kleshev, and define $\lambda(i)=(\lambda_1^{a_1},\ldots,\lambda_{i-1}^{a_{i-1}},\lambda_i^{a_i-1},\lambda_i^{a_i-1},\lambda_{i+1}^{a_{i+1}},\ldots,\lambda_l^{a_l})$ to be the partition with the ith row removed.

Fixing some partition λ , for $1 \le i \le j \le l$, let $\beta(i,j)$ be the hook length

$$\beta(i,j) = \lambda_i - \lambda_j + \sum_{t=i}^{j} a_t.$$

Then, adopting Kleshev's terminology, j is normal in λ if $\beta(i,j) \not\equiv 0 \pmod{e}$ for all i < j, and j is good if it is the largest normal number (these are stronger conditions than generally necessary).

Let $S^{(n+r,n)'}$ be the Specht module corresponding to the young diagram with two columns with height difference r, and let $D^{(n+r,n)'}$ be the corresponding irreducible quotient. The purpose of this writing is to characterize these representation via an isomorphism with two graphical representations of \mathcal{H} .

1.1. Crossingless Matchings.

Definition 1.1. A crossingless matching on 2n + r indices with r anchors is a partition of $\{1, \ldots, 2n + r\}$ into n parts of size 2 and r of size 1 such that no two parts of size two "cross", i.e. there are no parts (a, a') and (b, b') such that a < b < a' < b', and no parts of size one are "inside" of a part of size two, i.e. there are no c, (a, a') such that a < c < a'. We will call these arcs and anchors, respectively. Then, define W_{2n+r}^r to be the k-vector space with basis the set of generalized crossingless matchings on 2n + r indices with r anchors.

In order for this to be a \mathcal{H} -module, endow this with the action given by Figure 1; if a "loop" is created, scale by q+1, if a loop is not created and the action involves fewer than 2 anchors, deform into a new crossingless maching and scale by $q^{1/2}$, and if it involves two anchors, scale by 0. We verify that this is well-defined in appendix A.1.

Let the length of an arc (i,j) be l(i,j):=j-i+1. Note that the crossingless matchings on 2n indices with no anchors can all be identified with a list of n integers describing the lengths of the arcs from left to right; using this, we may order the crossingless matchings with no anchors in increasing lexicographical order in order to obtain an order on the subbasis containing a particular set of anchors; let the basis be ordered first by the position of the anchors in decreasing lexicographical order, then increasing for the matchings between each anchor. Let this basis be $\{w_i\}$. This basis is illustrated for W_5^1 in Figure 2.

We will prove that $W := W_{2n+r}^r$ and $S := S^{(n+r,n)'}$ are isomorphic as representations in the case that

We will prove that $W := W_{2n+r}^r$ and $S := S^{(n+r,n)}$ are isomorphic as representations in the case that e > n+r+1. Note that, when r=0, these have the same dimension given by the nth catalan number C_n .

1.2. **Fibonacci Representation.** Now suppose that $k = \mathbb{C}$ and $q = \exp(2\pi i \ell/5)$ is a primitive 5th root of unity. Let V^m be a k-vector space with basis given by the strings $\{*,p\}^{n+1}$ such that the character * never appears twice in a row. We will surpress the superscript whenever it is clear from context.

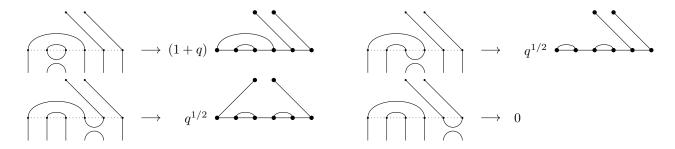

Figure 1. Illustration of the actions $(1+T_i)w_{|W_6^2|}$. In general, we act by deleting loops, deforming into a new crossingless matching, and scaling by either $q^{1/2}$, (q+1), or 0.

Figure 2. The basis for W_5^1 .

We wish to endow this with a \mathcal{H} -action which acts on a basis vector only dependent on characters i, i+1, i+2, sending each basis vector to a combination of the other basis vectors having the same characters $1, \ldots, i, i+2, \ldots, n+1$ as follows:

(1)
$$T_{1}(*pp) := \alpha(*pp)$$

$$T_{1}(pp*) := \alpha(pp*)$$

$$T_{1}(*p*) := \beta(*p*)$$

$$T_{1}(p*p) := \gamma(p*p) + \delta(ppp)$$

$$T_{1}(ppp) := \delta(p*p) + \varepsilon(ppp)$$

for constants

$$\beta = q$$

$$\gamma = \tau(q\tau - 1)$$

$$\delta = \tau^{3/2}(q+1)$$

$$\varepsilon = \tau(q-\tau)$$

$$\tau = \begin{cases} \frac{1}{2} \left(\sqrt{5} - 1\right) & \ell \equiv 1, 4 \pmod{5} \\ \frac{1}{2} \left(\sqrt{5} + 1\right) & \ell \equiv 2, 3 \pmod{5} \end{cases}$$

 $\alpha = -1$

with T_i acting similarly on the substring i, i+1, i+2. We will verify that this is a representation of \mathcal{H} in Appendix A.2

This contains 4 subrepresentations based on the first and last character of the string, which are not modified by \mathscr{H} . Label the subrepresentation of strings $(*\cdots*)$ by V_{**} , and similar for the other 3. It is easy to see that $V_{*p} \simeq V_{p*}$, so that

$$V \simeq 2V_{*p} \oplus V_{**} \oplus V_{pp}.$$

We will show that $V_{pp} \simeq V_{*p} \oplus V_{**}$, and give the following isomorphisms with irreducible quotients of specht modules depending on the parity of the number of indices in \mathcal{H} :

(3)
$$V_{**}^{2n} \simeq D^{(n,n)'}$$

$$V_{**}^{2n-1} \simeq D^{(n+1,n-2)'}$$

$$V_{*p}^{2n} \simeq D^{(n+1,n-1)'}$$

$$V_{*p}^{2n-1} \simeq D^{(n,n-1)'}.$$

2. Crossingless Matchings and Specht Modules

Our goal is to prove that $W^r_{2n+r} \simeq S^{(n+r,n)'}$ when e > n+r+1.

Proposition 2.1. (i) Suppose that n, r > 0. Then, a filtration of $ResW_{2n+r}^r$ is given by

$$(4) 0 \subset W^{r-1}_{2n+r-1} \subset \operatorname{Res} W^r_{2n+r}$$

with $Res W^r_{2n+r}/W^{r-1}_{2n+r-1} \simeq W^{r+1}_{2n+r-1}$.

(ii) We have the following isomorphism of representations:

$$(5) W_{2n-1}^1 \simeq \operatorname{Res} W_{2n}^0$$

Proof. (i) Note that we may identify the subrepresentation of Res W^r_{2n+r} having anchor n with W^{r-1}_{2n+r-1} . Let $U:=\operatorname{Res} W^r_{2n+r}/W^{r-1}_{2n+r-1}$. Let $\phi:U\to W^{r+1}_{2n+r-1}$ be the k-linear map which regards the arc (i,2n+r) in U as an anchor at i in W^{r+1}_{2n+r-1} . It is not hard to verify that this is a well-defined isomorphism of vector spaces, so we must show that it is \mathscr{H} -linear.

Given a basis vector w_j with arc (i, 2n+r), ϕ is clearly compatible with $T_{i'}$ with $i' \neq i, i-1$. Further, it's easy to verify that ϕ is compatible with T_i and T_{i-1} , as actions on one anchor were designed for this deformation. When there are anchors (i, i+1), then $\phi(T_i w_j) = T_i \phi(w_j) = 0$, and similar for T_{i-1} . Hence ϕ is an isomorphism of representations, and the statement is proven.

(ii) This follows with the above proof, defining
$$W_{2n-1}^{-1} := 0$$

Lemma 2.2. Every basis vector in W_{2n+r}^r is cyclic.

Proof. We have already proven this in the r = 0 case, so suppose that r > 0.

Note that, between anchors a < a' having no arc b with a < b < a', the $W_{a'-a}^0$ case allows us to generate the vector with all length-2 arcs between a, a' and identical arcs/anchors outside of this sub-matching.

Applying this between each arc gives us a vector with length-2 arcs and anchors, and we may use the appropriate $(1 + T_i)$ to move anchors to any positions, and the reverse process from above to generate the correct matchings between arcs and generate any other basis vector.

Let $K := \bigcap_{i=1}^{2n+r-1} \ker(1+T_i) = \ker \bigoplus_{i=1}^{2n+r-1} (1+T_i)$. This will be a large technical tool in our proof of irreducibility.

Lemma 2.3. Let w_j be the basis vector with anchors $1, \ldots, r$ and all arcs of maximal length. Suppose $w \in K \setminus \{0\}$. Then, w_i is represented in w.

Proof. We will show this in steps; first, we show that, given that a vector is represented with anchors $1, \ldots, s$, there must be a vector represented in w with (s+1)st anchor, including when s=0; this implies that a vector is represented with anchors $1, \ldots, r$. Then, we will show that, given a vector is represented with anchors $1, \ldots, r$ and first s arc-lengths $n, n-2, \ldots, n-2s$, there is a vector represented with these and the (s+1)st arc-length n-2s-2. This implies that w_j is represented.

Step 1. Suppose that s < r is the maximal number such that a vector with anchors $1, \ldots, s$ is represented. Take the vector w_i which, among vectors represented in w with anchors $1, \ldots, s$, has (s+1)st anchor at minimal index t > s+1, Then, $q^{-1/2}(1+T_{t-1})w_i$ has anchors $1, \ldots, s$ and a earlier index than t, so it was not represented before; further, for any other basis vector $w_l \neq w_i$ to map onto $q^{-1/2}(1+T_{t-1})w_i$, we would require that w_l has anchors $1, \ldots, s$ and some other anchor at index t' < t, so it is not represented. Hence w_i is unique among the vectors represented mapping onto $q^{-1/2}(1+T_{t-1})w_i$, and $(1+T_{t-1})w$ represents this vector, giving $w \notin \ker(1+T_{t-1})$.

When s=0, this is similar, and we simply perform this logic on the 1st anchor. Each lead to contradiction, so we must have s=r.

Step 2. This step is similar; suppose that s < n is the maximal number such that a vector with anchors $1, \ldots, r$ and first s arc-lengths $n, \ldots, n-2s$ is represented. Take the vector w_i which, among vectors represented in w with anchors $1, \ldots, r$ and first s arc-lenths $n, \ldots, n-2s$, has maximal length t of the arc beginning at index r+s+1. Then, $q^{1/2}(1+T_{r+s+t})w_i$ is mapped to only by w_i and vectors having anchors $1, \ldots, r$ and first s+1 arc-lengths $n, \ldots, n-2s, t'$ with t'>t, which are not represented in w; hence

¹At the ends, we apply the W_a^0 case or the W_{2n+r-a}^0 case in the same way for the first a or last 2n+r-a indices.

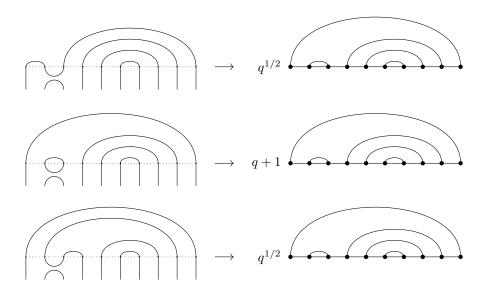

Figure 3. Illustrated is the row constructed for transposition $(1 + T_2)$; clearly these are the only basis elements mapping to multiples of the desired element, and they relate to each other. replacing the outermost and/or innermost arc with an anchor typifies the rows constructed with three nonzero coefficients.

 $q^{-1/2}(1+T_{r+s+t})w_i$ is represented in $(1+T_{r+s+t})w$, giving $w \notin \ker(1+T_{r+s+t})$. The s=0 case is similar, and implies that s=n.

Lemma 2.4. Suppose $e \nmid n + r + 1$. Then, K = 0.

Proof. Consider the matrix $A = \bigoplus (1 + T_i)$ having kernel K. It is sufficient by lemma 2.3 to show that A includes a row $[0, \ldots, 0, 1, 0, \ldots, 0]$ with a nonzero entry only on the column j.

Now, we may characterize the rows of A as follows; if the row corresponding to $(1 + T_i)$ and mapping onto the element $w_l \in W$ is nonzero, then it is of the form $[a_1, \ldots, a_{|W|}]$ where $a_l = 1 + q$, $a_m = q^{1/2}$ whenever $(1 + T_i)w_m = q^{1/2}w_l$, and $a_m = 0$ otherwise.

Seeing this, the row corresponding to $(1+T_{n+r})$ and w_j has nonzero entries $q^{1/2}$ at w_j and (1+q) at the vector w agreeing with w_j at all indices except having arcs at (n+r-1,n+r) and (n+r+1,n+r+2). Similar justification leads the row corresponding to $(1+T_{n+r-1})$ at w to have nonzero entries $q^{1/2}$ at w and (1+q) at w_j and the vector with anchors $1,\ldots,r$, arc (n+r-3,n+r-2), and all other arcs maximum length.

We may iterate this process as illustrated in Figure 3, eventually ending at a row with two nonzero entries, either an arc (1,2) or an arc (2,3), and all anchors otherwise left-aligned and arcs of maximum length. These rows together form an $(n+r) \times |W^r_{2n+r}|$ sumbatrix of A which has a nonzero column in the row corresponding to j, and has (by removing zero columns) the same column space as the following square matrix:

$$B_{n+r} := \begin{bmatrix} q+1 & q^{1/2} & & & & & & \\ q^{1/2} & q+1 & q^{1/2} & & & & & \\ & q^{1/2} & q+1 & q^{1/2} & & & & \\ & & \ddots & \ddots & & & \\ & & & & q^{1/2} & q+1 & q^{1/2} \\ & & & & & & q^{1/2} & q+1 \end{bmatrix}.$$

We will show that this matrix is invertible; then, a sequence of elementary row operations will yield the identity, and in particular, when applied to A, will yield a row with a nonzero entry only on column j, giving K = 0.

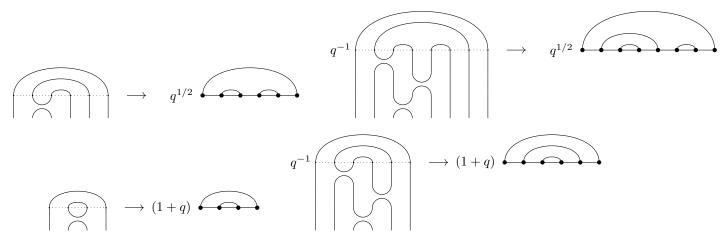

Figure 4. The correspondence between the action of $(1 + T_2)$ on $w'_5 \in W_6^0$ and the action of $q^{-1}(1 + T_3)(1 + T_4)(1 + T_2)$ on the corresponding vector in W_8^0 having arc (3,4) first, then on $w'_2 \in W_4^0$. This demonstrates that the action works with and without creating a loop.

We may prove invertibility of this matrix by proving that $\det B_{n+r} = [n+r+1]_q$ inductively on n+r. This is satisfied for our base case n+r=1, so supose that it is true for each m < n+r. Then,

$$\det B_{n+r} = (q+1) \det B_{n+r-1} - q \det B_{n+r-2}$$

$$= (q+1)(1+\dots+q^{n+r-1}) - (q+\dots+q^{n+r-1})$$

$$= 1+\dots+q^{n+r}$$

$$= [n+r+1]_q.$$

Hence $\det B_{n+r} \neq 0$, and K = 0.

Proposition 2.5. The representation W_{2n+r}^r is irreducible when e > n + r + 1.

Proof. We proceed by induction on 2n + r. Note that, by identification with the trivial and sign representations, the base case 2n + r = 2 is already prove, so suppose we have proven this for each 2m + s < 2n + r. Take some $w \in W$ and some $(1 + T_i)$ not annhialating w. Note that

$$\operatorname{im}(1+T_i) = \operatorname{Span}\{w_j \mid w_j \text{ contains arc } (i,i+1)\}.$$

Hence, as vector spaces, there is an isomorphism $\varphi: \operatorname{im}(1+T_i) \to W^r_{2(n-1)+r}$ "deleting" the arc (i,i+1). This sends every basis vector to another basis vector.

We will show that, for every action $(1 + T'_j) \in \mathcal{H}(S_{2(n-1)+r})$, there is some action $h_j \in W^r_{2n+r}$ such that the following commutes:

$$\operatorname{im}(1+T_i) \xrightarrow{\varphi} W_{2(n-1)+r}^r$$

$$\downarrow^{h_j} \qquad \downarrow^{1+T_j}$$

$$\operatorname{im}(1+T_i) \xrightarrow{\varphi} W_{2(n-1)+r}^r$$

Indeed, when $i \neq j$ this is given by $h_j = 1 + T_j$, and we have $h_i = q^{-1}(1 + T_i)(1 + T_{i+1})(1 + T_{i-1})$, as given by Figure 4.

Due to the inductive hypothesis, there is some action $h' \in \mathcal{H}(S_{2(n-1)+r})$ sending $\varphi((1+T_i)w)$ to a basis vector; then, the action \mathcal{H} generates the endomorphism $\varphi^{-1}h'\varphi$ sending $(1+T_i)w$ to a basis vector, giving w cyclic and hence W_{2n+r}^r irreducible.

Corollary 2.6. Suppose n, r > 0 and e > n + 1. Then, the sequence (4) is a composition series of $Res W_{2n+r}^r$.

Theorem 2.7. Suppose e > n + r + 1, n > 0. Then, $W_{2n+r}^r \simeq S^{(n+r,n)'}$.

Proof. By irreducibility, we know that $W_{2n+r}^r \simeq D^{\lambda}$ for some e-restricted partition λ . We will proceed in two steps; first we prove that $\lambda = (n+r,n)'$, then we prove that $S^{(n+r,n)'}$ is irreducible.

This will be done inductively; by identification with the trivial and sign representations, the 2n+r=2 caseholds, so suppose this is true for W^s_{2m+s} whenever 2m+s<2n+r and $m+s\leq n+r$ (i.e. e>m+s+1).

Step 1. By the inductive hypothesis and irreducibility, we have a composition series given by

$$(6) 0 \longrightarrow D^{(n+r-1,n)'} \longrightarrow \operatorname{Res} D^{\lambda} \longrightarrow D^{(n+r,n-1)'} \longrightarrow 0$$

In particular, by the Jordan-Hölder theorem, if we have some module $D^{\mu} \subset \text{Res } D^{\lambda}$, then $\mu = (n+r-1,n)'$ or $\mu = (n+r,n-1)'$.

By Kleschev, we know that $soc(D^{\lambda}) = \bigoplus_{\mu} D^{\mu}$, where μ ranges over $\lambda(i)$ for every good number i of λ . Immediately this narrows down λ to three options; the only λ with some $\lambda(i)$ giving (n+r-1,n)' are $\lambda_1 := (n+r-1,n,1)'$, $\lambda_2 = (n+r-1,n+1)'$, and $\lambda_3 = (n+r,n)'$.

Note numbers $\beta_l(i,j)$ correspond to hook-lengths, and each λ ; has maximum hook length n+r+1; hence $\beta_l(i,j) \not\equiv 0 \pmod{e}$ for all i,j,l, and 3 is a good number in λ_1 and 2 in λ_2 . This implies $D^{(n+r-2,n,1)'} \subset D^{\lambda_1}$ and $D^{(n+r-2,n+1)'} \subset D^{\lambda_2}$, giving that $\lambda = \lambda_3$ as desired.

Step 2. Let the hook length of node (a,b) in $[\lambda]$ be written h_{ab}^{λ} . Let $\nu_p(h_{ab}^{\lambda})$ be the p-adic valuation of h_{ab}^{λ} , and let $\nu_{e,p}(h_{ab}^{\lambda})$ be $\nu_p(h^J)$. Mathas Theorem 5.42 says, for λ e-restricted, S^{λ} is irreducible if $\nu_{e,p}(h_{ab}^{\lambda}) = \nu_{e,p}(h_{ac}^{\lambda})$ for a suitable prime p. In particular, since $h_{ab}^{\lambda} < e$ for all a,b, we have $\nu_{e,p}(h_{ab}^{\lambda}) = -1$ for all a,b, and S^{λ} is irreducible.

3. The Fibonacci Representation and Specht Modules

We can start our study of V by studying low-dimensional cases. First, note that V_{*p}^2 is the sign representation $D^{(2)}$ and V_{**}^2 is the trivial representation $D^{(1)^2}$.

 V_{pp}^2 is a 2-dimensional representation of a semisimple commutative algebra, and hence decomposes into a direct sum of two subrepresentations. In particular, we can use the basis $\{(p*p), (ppp)\}$ and explicitly write the matrix

$$\rho_{T_1} = \begin{bmatrix} \gamma & \delta \\ \delta & \varepsilon \end{bmatrix}$$

having characteristic polynomial $(c-\lambda)(e-\lambda)-d^2=\lambda^2-(c+e)\lambda+(ce-d^2)$. The reader can verify that this has roots -1 and q. The eigenspaces with eigenvalues -1 and q are subrepresentations isomorphic to the sign and trivial representation, hence F_{pp} is isomorphic to a direct sum of the trivial and sign representations: $V_{pp}^2 \simeq V_{*p}^2 \oplus V_{**}^2$.

Now let's prove that V_{**}^3 is irreducible; this has basis $\{*p*p\}$, $\{*ppp\}$, and the following matrices:

$$\rho_{T_1} = \begin{bmatrix} \beta & 0 \\ 0 & \alpha \end{bmatrix}; \qquad \rho_{T_2} = \begin{bmatrix} \gamma & \delta \\ \delta & \varepsilon \end{bmatrix}.$$

A subrepresentation must be one-dimensional, and hence an eigenspace of each of these matrices; since $\beta \neq \alpha$, the first has eigenspaces given by the spans of basis elements, and since $\delta \neq 0$, these are not eigenspaces of the second. Hence V_{**}^3 is irreducible. Now we may move on to the general case.

Proposition 3.1. The representation $V_{*p} := V_{*p}^m$ is irreducible.

Proof. We will prove this inductively in m. We've already proven it for V_{*p}^2 and V_{*p}^3 , so suppose that V_{*p}^{m-2} is irreducible.

Let $\{v_i\}$ be the basis for V_{*p} . Then, each v_i is cyclic; indeed, we can transform every basis vector into $(*p \dots p)$ by multiplying by the appropriate $\frac{1}{\delta - \gamma}(T_i - \gamma)$, and we can transform $(*p \dots p)$ into any basis vector by multiplying be the appropriate $\frac{1}{\delta - \varepsilon}(T_i - \varepsilon)$. Hence it is sufficient to show that each $v \in V_{*p}$ generate some basis element.

Let v' be the basis element (*p*p...p), which is many copies of *p, followed by an extra p if m is odd. We will show that each $v \in F$ generates v'.

Suppose that no elements beginning (*p*p) are represented in v_i ; then, all such elements are represented in T_3v , so we may assume that at least one is represented in v.

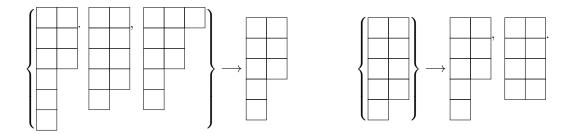

Figure 5. Illustration of the partitions of 9 which can, via row removal, yield (n, n-2)' alone, or both (n, n-2)' and (n-1, n-1)'.

Note that $\operatorname{im}(T_2 - \alpha) = \operatorname{Span}\{\operatorname{Basis} \text{ vectors beginning } (*p*p)\}$ and $(T_2 - \alpha)v \neq 0$. Further, note that $\operatorname{Res}_{\mathcal{H}(S_{m-2})}^{\mathcal{H}(S_m)}\operatorname{im}(T_2 - \alpha) \simeq V_{*p}^{m-2}$ as representations. Hence irreducibility of V_{*p}^{m-2} implies that v' is generated by $(T_2 - \alpha)v$, and V_{*p}^m is irreducible.

Knowing this, the restriction statements are clear; $\operatorname{Res} V^m_{*p} \simeq V^{m-1}_{pp}$ by considering the last m-2 transpositions, and $\operatorname{Res} V^{m-1}_{*p} \simeq V^{m-1}_{*p} \oplus V^{m-1}_{**}$ by considering the first m-2. Similarly, $\operatorname{Res} V^m_{**} \simeq V^{m-1}_{*p}$ by considering the first m-2 transpositions. This gives that $V \simeq 3V_{*p} \oplus 2V_{**}$.

Now we may move on and use Young Tableau to characterize V. Recall that the socle of D^{λ} is given by $\bigoplus_{\mu \xrightarrow{\text{good}} \lambda} D^{\mu}$, and that D^{λ} is semisimple iff every $\mu \xrightarrow{\text{normal}} \lambda$ is good.

Theorem 3.2. The irreducible components of V are given by the following isomorphisms:

$$\begin{split} V_{**}^{2n} &\simeq D^{(n,n)'} \\ V_{**}^{2n-1} &\simeq D^{(n+1,n-2)'} \\ V_{*p}^{2n} &\simeq D^{(n+1,n-1)'} \\ V_{*p}^{2n-1} &\simeq D^{(n,n-1)'}. \end{split}$$

Proof. We will prove this by induction on n; we have already proven the base case V^2 , so suppose that we have proven these isomorphisms for V^{2n-2} . We will prove the isomorphisms for V^{2n-1} and V^{2n} .

By irreducibility, $V_{**}^{2n-1} \simeq D^{\lambda_{**}}$ and $V_{*p}^{2n-1} \simeq D^{\lambda_{*p}}$ for some diagrams λ_{**} and λ_{*p} . We will show that $\lambda_{**} = (n+1, n-2)'$ and $\lambda_{*p} = (n+1, n-1)'$.

First, note that we have

Res
$$D^{\lambda_{**}} \sim D^{(n,n-2)'} \sim \text{Res } D^{(n+1,n-2)'}$$

and

Res
$$D^{\lambda_{*p}} \simeq D^{(n,n-2)} \oplus D^{(n-1,n-1)} \simeq \text{Res } D^{(n,n-1)'}$$
.

By semisimplicity of $\operatorname{Res} D^{\lambda_{**}}$ and $\operatorname{Res} D^{\lambda_{*p}}$, every normal cell in λ_{**} and λ_{*p} is good, and every good cell is removed in a summand of the restriction. In particular, the only normal number in λ_{**} is 1.

For λ_{**} , the only tableaux which can remove a cell to yield $D^{(n,n-2)'}$ are (n+1,n-2)', (n,n-1)', and (n,n-2,1)' as illustrated in Figure 5; we have already seen that $D^{(n,n-1)'}$ does not have irreducible restriction, so we are left with (n+1,n-2)' and (n,n-2,1)'. We may directly check that (n,n-2,1)' doesn't satisfy this, as we have the following:

$$\beta_{\lambda}(1,2) = 3 - 2 + (n-2) = n - 1$$

$$\beta_{\lambda}(1,3) = 3 - 1 + n = n + 2$$

$$\beta_{\lambda}(2,3) = 2 - 1 + 3 = 4.$$

At least one of $\beta(1,2)$ and $\beta(1,3)$ is nonzero, since $\beta_{\lambda}(1,3) - \beta_{\lambda}(1,2) = 3 \not\equiv 0 \pmod{e}$, and hence at least one of M_2 and M_3 is empty. Hence at least one of 2 or 3 is normal in (n, n-2, 1)', and $\lambda_{**} = (n+1, n-2)$. For λ_{*p} , we immediately see from Figure 5 that the only option is (n, n-1).

We can perform a similar argument for the V^{2n} case, finding now that

Res
$$D^{\mu_{**}} \simeq D^{(n,n-1)'} \simeq \text{Res } D^{(n,n)'}$$

and

Res
$$D^{\mu_{*p}} \simeq D^{(n,n-1)'} \oplus D^{(n+1,n-2)'} \simeq \text{Res } D^{(n+1,n-1)'}$$
.

Through a similar process, we see that $\mu_{*p} = (n+1, n-1)'$. We narrow down μ_{**} to one of (n, n)' or (n, n-1, 1)', and note that

$$\beta_{\mu}(1,2) = 3 - 2 + (n-1) = n$$

$$\beta_{\mu}(1,3) = 3 - 1 + n = n + 2$$

$$\beta_{\mu}(2,3) = 2 - 1 + 2 = 3$$

and hence at least one of 2 or 3 is normal, $\operatorname{Res} D^{(n,n-1,1)'}$ is not irreducible, and $\mu_{**}=(n,n)'$, finishing our proof.

Corollary 3.3. We have the following isomorphisms of representations:

$$V^{2n} \simeq 3D^{(n+1,n-1)'} \oplus 2D^{(n,n)'}V^{2n-1} \simeq 3D^{(n,n-1)'} \oplus 2D^{(n+1,n-2)'}$$

4. Explicit Relationships

APPENDIX A. COMPATIBILITY OF REPRESENTATIONS WITH THE RELATIONS

In general, we define representations above for the free algebra on generators $\{T_i\}$. Recall that we may give a presentation of \mathscr{H} having generators T_i and relations

$$(7) (T_i - q)(T_i + 1) = 0$$

(8)
$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

(9)
$$T_i T_j = T_j T_i \qquad |i - j| > 1.$$

We call (7) the quadratic relation and (8), (9) the braid relations. It is easily seen that a representation of \mathcal{H} is equivalent to a representation of the free algebra $k\langle T_i \rangle$ which acts as 0 on the relations (henceforth referred to as compatibility with the relations). We will prove in the following sections that V and W are compatible with the Hecke algebra relations.

A.1. The Crossingless Matchings Representation. Take some basis vector w_i . We will first check (7) by case work:

- Suppose there is an arc (i, i+1). Then, $(T_i q)(T_i + 1)w = (1+q)[(1+T_i)w (1+q)w] = 0$, giving (7).
- Suppose there is no arc (i, i + 1) and i, i + 1 do not both have anchors; then $(T_i + 1)w = q^{1/2}w''$ for some basis vector w' having arc (i, i + 1), and the computation follows as above for (7).
- Suppose i, i + 1 are anchors; then $(T_i + 1)w = 0$, giving (7).

Now we verify (8). Let $h := (1 + T_i)(1 + T_{i+1})(1 + T_i)$, and let $g := (1 + T_{i+1})(1 + T_i)(1 + T_{i+1})$. Note the following expansion:

$$hw = 1 + 2T_i + T_i^2 + T_{i+1} + T_i T_{i+1} + T_{i+1} T_i + T_i T_{i+1} T_i$$

= 1 + (1 + q)T_i + T_{i+1} + T_iT_{i+1} + T_{i+1}T_i + T_iT_{i+1}T_i.

An analogous formula gives an analogous equality in g. Hence we have

$$(h-g)w = q(T_i - T_{i+1}) + T_i T_{i+1} T_i - T_{i+1} T_i T_{i+1}.$$

Hence we may equivalently check that $(h-q)w=q(T_i-T_{i+1})$. This is illustrated in Figure 6.

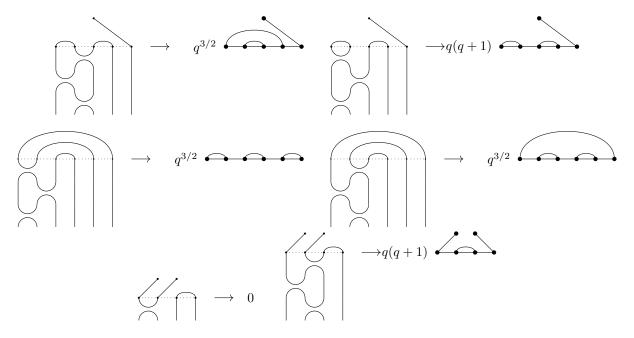

Figure 6. Here we verify in small cases that $hw = qT_i$ and $gw = qT_{i+1}$. These 6 cases cover the situations that there is an arc among the indices i, i+1, i+2, that there isn't and there are not two arcs, and that there are two arcs.

Lastly, we have the equation

$$(1+T_i)(1+T_j) - (1+T_j)(1+T_i) = T_iT_j - T_jT_i$$

and hence we simply need to verify that $(1+T_i)$ and $(1+T_i)$ commute, which the reader may easily check.

A.2. **The Fibonacci Representation.** Similar to before, the reader may verify that (9) follows easily, and the others may be verified on strings of length 3 and 4. By considering the coefficients in order of (1), the quadratic relation (7) gives the following quadratics:

(10)
$$(\alpha - q)(\alpha + 1) = 0$$
$$(\beta - q)(\beta + 1) = 0$$
$$\gamma \delta + \delta \varepsilon = (q - 1)\delta$$
$$\gamma^2 + \delta^2 = (q - 1)\gamma + q$$
$$\varepsilon^2 + \delta^2 = (q - 1)\varepsilon + q$$

The first two of these are easily verified for any q. Since $\delta \neq 0$, the third is equivalently given by

$$(q-1) = \gamma + \varepsilon = t(q\tau - 1 + q - \tau) = (\tau^2 + \tau)(q-1)$$

or that $(\tau^2 + \tau - 1)(q - 1) = 0$. The reader may verify that $\tau^2 + \tau - 1 = 0$, so this is true for every q. The fourth is given by the quadratic

$$\tau^{2} \left[(q\tau - 1)^{2} - \tau(q+1) \right] = \tau(q-1)(q\tau - 1) + q$$

or equivalently,

$$(\tau^2 + \tau - 1) [q (qt^2 + 1) + t] = 0$$

which is true for every q.

The fifth is similarly given by

$$(\tau^2 + \tau - 1) \left[q (qt + 1) + t^2 \right] = 0$$

which is true for every q.

We now verify (8). We may order the basis for V^4 as follows:

$$\{(pppp), (*pp*), (ppp*), (*ppp), (*p*p), (p*p*), (p*p*), (p*pp)\}.$$

Then, in verifying the braid relation (8) in this order, we encounter the following quadratics (with tautologies and repetitions omitted):

$$\alpha \varepsilon^{2} + \beta \delta^{2} = \alpha^{2} \varepsilon$$

$$\alpha \delta \varepsilon + \beta \gamma \delta = \alpha \beta \delta$$

$$\beta \gamma^{2} + \alpha \delta^{2} = \beta^{2} \gamma$$

$$\alpha \gamma^{2} + \delta^{2} \varepsilon = \alpha^{2} \gamma$$

$$\delta \varepsilon^{2} + \alpha \gamma \delta = \alpha \delta \varepsilon$$

The reader may verify that each of these are satisfied for q a primitive 5th root of unity and τ as defined.

This highlights the difficulty with deforming our module to q=1 at any field; the quadratic relations require that $(\tau^2+\tau-1)(\tau^2+\tau+1)=0$, but neither of these appear in the first braid relation, which reads $\tau(\tau^3-6\tau^2+1)=0$. If we have $\tau^2+\tau\pm 1=0$, then $\tau\neq 0$ and $-7\tau^2\pm \tau+1=0$. Hence $(7\pm 1)\tau+(1\pm 1)=0$, implying that $\tau=\frac{1}{4},0$, neither of which satisfy $\tau^2+\tau\pm 1=0$, a contradiction.

To attempt to deform this to q=1 would require that we rewrite $\gamma, \delta, \varepsilon$ entirely, rather than simply modifying τ .

APPENDIX B. MISCELLANEOUS ALGEBRA FACTS

Throughout the text, for some representation V, we refer to $\operatorname{Res}_{\mathscr{H}(S_l)}^{\mathscr{H}(S_m)}V$ without specifying exactly which subalgebra $\mathscr{H}(S_l)$.

Proposition B.1. Suppose B, B' are subalgebras of the k-algebra A with $B = uB'u^{-1}$, and let V be a representation of A. Then, the linear isomorphism $V \xrightarrow{\phi} V$ given by $v \mapsto uv$ causes the following to commute for any $b \in B$:

$$V \xrightarrow{\phi} V$$

$$\downarrow b \qquad \downarrow ubu^{-1}$$

$$V \xrightarrow{\phi} V$$

Hence, through the identification of B and B' via conjugation, we have $Res_B^A V \simeq Res_{B'}^A V$

Proof. This is simply given by $(ubu^{-1})uv = ubv$.

Corollary B.2. Suppose $\mathcal{H}', \mathcal{H}''$ are two subalgebras of $\mathcal{H}(S_m)$ generated by l reflections and V is a representation of \mathcal{H} . Then, $Res_{\mathcal{H}'}^{\mathcal{H}}V \simeq Res_{\mathcal{H}''}^{\mathcal{H}}V$.

Proof. Let \mathscr{H}' and \mathscr{H}'' be the subalgebras of $\mathscr{H}(S_m)$ generated by the reflections $\{T_{i_1},\ldots,T_{i_l}\}$ and $\{T_{i_1},\ldots,T_{i_{j-1}},T_{i_{j+1}},T_{i_{j+1}},\ldots,T_{i_l}\}$ for $1\leq i_1<\cdots< i_{j-1}< i_j+1< i_{j+1}<\cdots< i_l\leq n$. It is sufficient to prove that \mathscr{H}' and \mathscr{H}'' are conjugate; then transitivity gives conjugacy of any $S_l\subset S_m$, and the previous proposition gives isomorphisms of the representations.

In fact, the reader can verify that $\mathscr{H}'' = T_{i_j} \mathscr{H}' T_{i_j}^{-1}$.
